

GIT DIFF – EASY LEARNING NOTES

What is git diff?

The *git diff* command is used to find the differences between file versions. It shows what changes were made in a file compared to the previous version.

When is git diff used?

- To check what changes you have made in a file - To review changes before adding them to the staging area - To understand exactly what was modified (line by line)

git diff (before staging)

If you have modified a file but have NOT added it to the staging area, use:

git diff

This command shows the difference between: • Working Directory • Last committed version (Local Repository)

git diff --staged (after staging)

If the file is already added to the staging area using:

git add filename

Then use the command:

git diff --staged

This shows the difference between: • Staging Area • Last committed version

Important Note

- *git diff* does NOT show committed changes - It only shows changes that are not yet committed

Simple Flow to Remember

Modify File → *git diff* → *git add* → *git diff --staged* → *git commit*
