

GIT FLOW AFTER MODIFYING AN EXISTING FILE – EASY LEARNING

Overview

This section explains what happens in GIT after you modify an existing file and how the file moves through different stages until it is saved permanently.

Step 1: Modify a file in Working Directory

First, you modify any existing file or folder in your project. This change happens in the **Working Directory** only.

Step 2: Check file status using git status

Run the command:

```
git status
```

GIT will show the file as **Modified**, which means the file has changes but is not yet staged or committed.

Step 3: Add file to Staging Area

To prepare the modified file for commit, move it to the Staging Area using:

```
git add filename
```

Now the file is staged and ready to be committed.

Step 4: Commit the staged file

Once the file is in the Staging Area, commit it using:

```
git commit -m "Commit message"
```

After commit, the file is saved permanently in the **Local Repository** with a new version.

Optional Step: Skip Staging Area for modified files

If you want to move modified files directly from the Working Directory to the Local Repository (without using git add), use:

```
git commit -a -m "Commit message"
```

Important Note

The -a option works only for files that are already tracked by GIT. It does NOT work for new (untracked) files.

Simple Flow to Remember

Working Directory → git status → git add → git commit → Local Repository
