

REMOVING A FILE FROM GIT – EASY LEARNING NOTES

Scenario

Sometimes a file is already committed to the local Git repository, but later you decide that the file should no longer be tracked by Git.

Important Understanding

Removing a file from Git is a two-step process: • Remove the file from Git tracking (repository) • Then remove the file from the working directory (if required)

Step 1: Remove the file from Git repository (stop tracking)

Use the following command:

```
git rm --cached filename
```

This command: • Removes the file from Git tracking • Keeps the file safely in the working directory

Step 2: Delete the file from Working Directory (optional)

After removing the file from Git tracking, you can delete the file manually from the project folder if it is no longer needed.

Step 3: Commit the change

Finally, save this change in Git history using:

```
git commit -m "Removed file from Git tracking"
```

Important Notes

• *git rm --cached* is commonly used when a file was committed by mistake • Useful for removing configuration files, logs, or sensitive files from Git tracking

Simple Flow to Remember

Committed File → *git rm --cached* → (optional delete file) → *git commit*
